2.5 Transition Metals
General properties of transition metals

transition metal characteristics of elements Sc → Cu arise from an incomplete d sub-level in atoms or ions

these characteristics include:
- complex formation,
- formation of coloured ions,
- variable oxidation state
- catalytic activity.

Why is Zn not a transition metal?
Zn can only form a +2 ion. In this ion the Zn²⁺ has a complete d orbital and so does not meet the criteria of having an incomplete d orbital in one of its compounds.

Complex formation

complex: is a central metal ion surrounded by ligands.

ligand: An atom, ion or molecule which can donate a lone electron pair.

Co-ordinate bonding is involved in complex formation. Co-ordinate bonding is when the shared pair of electrons in the covalent bond come from only one of the bonding atoms.

Co-ordination number: The number of co-ordinate bonds formed to a central metal ion.

Ligands can be monodentate (e.g. H₂O, NH₃ and Cl⁻) which can form one coordinate bond per ligand or bidentate (e.g. NH₂CH₂CH₂NH₂ and ethanedioate ion C₂H₂O₄²⁻) which have two atoms with lone pairs and can form two coordinate bonds per ligand or multidentate (e.g. EDTA⁴⁻ which can form six coordinate bonds per ligand).

Substitution Reactions

H₂O, NH₃ and Cl⁻ can act as monodentate ligands.
The ligands NH₃ and H₂O are similar in size and are uncharged.
Exchange of the ligands NH₃ and H₂O occurs without change of co-ordination number (eg Co²⁺ and Cu²⁺).

\[\text{[Co(H₂O)₆]²⁺(aq) + 6NH₃(aq) \rightarrow [Co(NH₃)₆]²⁺(aq) + 6H₂O(l)}\]

This substitution may, however, be incomplete as in the case with Cu.

\[\text{[Cu(H₂O)₆]²⁺(aq) + 4NH₃(aq) \rightarrow [Cu(NH₃)₄(H₂O)₂]²⁺(aq) + 4H₂O(l)}\]

Cu becomes [Cu(NH₃)₄(H₂O)₂]²⁺ deep blue solution

Reactions with Chloride Ions

Addition of a high concentration of chloride ions (from conc HCl or saturated NaCl) to an aqueous ion leads to a ligand substitution reaction.

The Cl⁻ ligand is larger than the uncharged H₂O and NH₃ ligands so therefore ligand exchange can involve a change of co-ordination number.

Be careful: If solid copper chloride (or any other metal) is dissolved in water it forms the aqueous [Cu(H₂O)₆]²⁺ complex and not the chloride [CuCl₂]²⁻ complex.
Bidentate Ligands

Ligands can be **bidentate** (e.g. \( \text{NH}_2\text{CH}_2\text{CH}_2\text{NH}_2 \) and ethanedioate ion \( \text{C}_2\text{O}_4^{2-} \)) which have two atoms with lone pairs and can form two coordinate bonds per ligand.

**Ethane-1-2-diamine**

![Ethane-1-2-diamine diagram]

Ethane-1-2-diamine is a common bidentate ligand.

A complex with Ethane-1-2-diamine bidentate ligands e.g. \([\text{Cr(NH}_2\text{CH}_2\text{CH}_2\text{NH}_2)_{3}]^{3+}\)

There are 3 bidentate ligands in this complex each bonding in twice to the metal ion.

It has a coordination number of 6

**Ethanedioate** \( \text{C}_2\text{O}_4^{2-} \)

![Ethanedioate diagram]

A complex with bidentate ethanedioate ligands e.g. \([\text{Cr(C}_2\text{O}_4)_{3}]^{3+}\)

Octahedral shape with 90° bond angles

**Equations to show formation of bidentate complexes**

\[
[\text{Cu(H}_2\text{O)}_{6}]^{2+} + 3\text{NH}_2\text{CH}_2\text{CH}_2\text{NH}_2 \rightarrow [\text{Cu(NH}_2\text{CH}_2\text{CH}_2\text{NH}_2)_{3}]^{2+} + 6\text{H}_2\text{O}
\]

\[
[\text{Cu(H}_2\text{O)}_{6}]^{2+} + 3\text{C}_2\text{O}_4^{2-} \rightarrow [\text{Cu(C}_2\text{O}_4)_{3}]^{4+} + 6\text{H}_2\text{O}
\]

Partial substitution of ethanedioate ions may occur when a dilute aqueous solution containing ethanedioate ions is added to a solution containing aqueous copper(II) ions. In this reaction four water molecules are replaced and a new complex is formed.

\[
[\text{Cu(H}_2\text{O)}_{6}]^{2+} + 2\text{C}_2\text{O}_4^{2-} \rightarrow [\text{Cu(C}_2\text{O}_4)_{2}(\text{H}_2\text{O})_{2}]^{2-} + 4\text{H}_2\text{O}
\]

**Multidentate Ligands**

Ligands can be **multidentate** (e.g. EDTA\(^4^-\)) which can form six coordinate bonds per ligand.

**The EDTA\(^4^-\) anion has the formula**

![EDTA anion diagram]

with six donor sites (4O and 2N) and forms a 1:1 complex with metal(II) ions

**Equations to show formation of multidentate complexes**

\[
[\text{Cu(H}_2\text{O)}_{6}]^{2+} + \text{EDTA}^{4-} \rightarrow [\text{Cu(EDTA)}]^{2-} + 6\text{H}_2\text{O}
\]

Learn the two bidentate ligands mentioned above but it is not necessary to remember the structure of EDTA.

Haem is an iron(II) complex with a multidentate ligand.

Oxygen forms a co-ordinate bond to Fe(II) in haemoglobin, enabling oxygen to be transported in the blood.

CO is toxic to humans as CO can form a strong coordinate bond with haemoglobin. This is a stronger bond than that made with oxygen and so it replaces the oxygen attaching to the haemoglobin.
Stability of complexes

The substitution of monodentate ligand with a bidentate or a multidentate ligand leads to a more stable complex. This is called the chelate effect

This chelate effect can be explained in terms of a positive entropy change in these reactions as more molecules of products than reactants

\[
[Cu(H_2O)_6]^{2+} \text{(aq)} + \text{EDTA}^{4-} \text{(aq)} \rightarrow [Cu(\text{EDTA})]^{2-} \text{(aq)} + 6H_2O \text{(l)}
\]

The copper complex ion has changed from having unidentate ligands to a multidentate ligand. In this reaction there is an increase in the entropy because there are more moles of products than reactants (from 2 to 7), creating more disorder.

The enthalpy change is small as there are similar numbers of bonds in both complexes.

**Free energy** \( \Delta G \) will be negative as \( \Delta S \) is positive and \( \Delta H \) is small.

The stability of the EDTA complexes has many applications. It can be added to rivers to remove poisonous heavy metal ions as the EDTA complexes are not toxic. It is in many shampoos to remove calcium ions present in hard water, so helping lathering.

\[
[\text{Co(NH}_3)_6]^{2+} + 3\text{NH}_2\text{CH}_2\text{CH}_2\text{NH}_2 \rightarrow [\text{Co(NH}_2\text{CH}_2\text{CH}_2\text{NH}_2)_3]^{2+} + 6\text{NH}_3
\]

This reaction has an increase in entropy because of the increase in moles from 4 to 7 in the reaction. \( S \) is positive.

Its enthalpy change \( H \) is close to zero as the number of dative covalent and type (N to metal coordinate bond) are the same so the energy required to break and make bonds will be the same. Therefore Free energy \( \Delta G \) will be negative and the complex formed is stable.

**EDTA titrations**

The formation of the stable EDTA complex with metal ions can with the choice of suitable indicator be done in a quantitative titration.

\[
[Cu(H_2O)_6]^{2+} + \text{EDTA}^{4-} \rightarrow [Cu(\text{EDTA})]^{2-} + 6H_2O \quad \text{Always the same 1:1 ratio with any metal ion}
\]

A river was polluted with copper(II) ions. 25.0 cm\(^3\) sample of the river water was titrated with a 0.0150 mol dm\(^{-3}\) solution of EDTA\(^{4-}\), 6.45 cm\(^3\) were required for complete reaction.

Calculate the concentration, in mol dm\(^{-3}\), of copper(II) ions in the river water.

**Step 1** : find moles of EDTA\(^{4-}\):

\[
\text{moles} = \text{conc} \times \text{vol} = 0.0150 \times 6.45/1000 = 9.68 \times 10^{-5} \text{ mol}
\]

**Step 2** : using balanced equation find moles Cu\(^{2+}\):

1:1 ratio

\[
= 9.68 \times 10^{-5} \text{ mol}
\]

**Step 3** : find conc Cu\(^{2+}\) in 25cm\(^3\)

\[
= 9.68 \times 10^{-5} / 0.025 = 0.00387 \text{ moldm}^{-3}
\]
Shapes of complex ions

Transition metal ions commonly form octahedral complexes with small ligands (e.g. H₂O and NH₃). [Co(NH₃)₆]²⁺ [Cu(H₂O)₆]²⁺

Transition metal ions commonly form tetrahedral complexes with larger ligands (e.g. Cl⁻). [CoCl₄]²⁻

Square planar complexes are also formed, e.g. cisplatin

Ag⁺ commonly forms linear complexes e.g. [Ag(NH₃)₂]⁺ used as Tollen’s Reagent

Isomerism in complex ions

Complexes can show two types of stereoisomerism: cis-trans isomerism and optical isomerism

Cis-trans isomerism in square planar complexes

Cis-Ni(NH₃)₂Cl₂

trans-Ni(NH₃)₂Cl₂

cis–trans isomerism is a special case of E–Z isomerism

Cis-trans isomerism in octahedral complexes

Cis-[Cr(H₂O)₄Cl₂]⁺

trans-[Cr(H₂O)₄Cl₂]⁺

Optical isomerism in octahedral complexes

Complexes with 3 bidentate ligands can form two optical isomers (non-superimposable mirror images).
Formation of coloured ions

**Colour** changes arise from changes in:
1. oxidation state,
2. co-ordination number
3. ligand.

### How colour arises

Colour arises from **electronic transitions** from the **ground state to excited states**: between different d orbitals. A **portion of visible light is absorbed** to promote d electrons to higher energy levels. The **light that is not absorbed is transmitted** to give the substance colour.

**Equation to learn!**

This equation links the colour and frequency of the light absorbed with the energy difference between the split d orbitals.

$$ \Delta E = h \nu $$

- $\nu$ = frequency of light absorbed (unit s⁻¹ or Hz)
- $h$ = Planck’s constant $6.63 \times 10^{-34}$ (J s)
- $\Delta E$ = energy difference between split orbitals (J)

**Changing colour**

Changing a ligand or changing the coordination number will alter the energy split between the d orbitals, changing $\Delta E$ and hence change the frequency of light absorbed.

### Compounds without colour

Scandium is a member of the d block. Its ion (Sc³⁺) hasn’t got any d electrons left to move around. So there is not an energy transfer equal to that of visible light.

In the case of Zn²⁺ ions and Cu⁺ ions the d shell is full e.g.3d¹⁰ so there is no space for electrons to transfer. Therefore there is not an energy transfer equal to that of visible light.

### Spectrophotometry

If visible light of increasing frequency is passed through a sample of a coloured complex ion, some of the light is absorbed. The amount of light absorbed is proportional to the concentration of the absorbing species (and to the distance travelled through the solution).

Some complexes have only pale colours and do not absorb light strongly. In these cases a suitable ligand is added to intensify the colour.

Absorption of visible light is used in spectrometry to determine the concentration of coloured ions.

**method**

- Add an appropriate ligand to **intensify** colour
- Make up solutions of known concentration
- Measure absorption or transmission
- Plot graph of absorption vs concentration
- Measure absorption of unknown and compare

Spectrometers contain a coloured filter. The colour of the filter is chosen to allow the wavelengths of light through that would be most strongly absorbed by the coloured solution.

N Goalby chemrevise.org
Variable oxidation states

Transition elements show variable oxidation states.

When transition metals form ions they lose the 4s electrons before the 3d.

General trends
• Relative stability of +2 state with respect to +3 state increases across the period
• Compounds with high oxidation states tend to be oxidising agents e.g MnO₄⁻
• Compounds with low oxidation states are often reducing agents e.g V²⁺ & Fe²⁺

The redox potential for a transition metal ion changing from a higher to a lower oxidation state is influenced by pH and by the ligand.

Vanadium

Vanadium has four main oxidation states
VO₂⁺ Oxidation state +5 (a yellow solution)
VO²⁺ Oxidation state + 4 (a blue solution)
V³⁺ Oxidation state + 3 (a green solution)
V²⁺ Oxidation state + 2 (a violet solution)

Addition of zinc to the vanadium (V) in acidic solution will reduce the vanadium down through each successive oxidation state, and the colour would successively change from yellow to blue to green to violet.

Manganate Redox Titration

The redox titration between Fe²⁺ with MnO₄⁻ (purple) is a very common exercise. This titration is self indicating because of the significant colour change from reactant to product.

MnO₄⁻(aq) + 8H⁺ (aq) + 5Fe²⁺ (aq) → Mn²⁺ (aq) + 4H₂O (l) + 5Fe³⁺ (aq)

The purple colour of manganate can make it difficult to see the bottom of the meniscus in the burette.

If the manganate is in the burette then the end point of the titration will be the first permanent pink colour.

Colourless → purple

Choosing correct acid for manganate titrations.

The acid is needed to supply the 8H⁺ ions. Some acids are not suitable as they set up alternative redox reactions and hence make the titration readings inaccurate.

Only use dilute sulfuric acid for manganate titrations.

Insufficient volumes of sulfuric acid will mean the solution is not acidic enough and MnO₂ will be produced instead of Mn²⁺.

MnO₂ (aq) + 4H⁺(aq) + 3e⁻ → Mn²⁺ (s) + 2H₂O

The brown MnO₂ will mask the colour change and lead to a greater (inaccurate) volume of manganate being used in the titration.

Using a weak acid like ethanoic acid would have the same effect as it cannot supply the large amount of hydrogen ions needed (8H⁺).

It cannot be conc HCl as the Cl⁻ ions would be oxidised to Cl₂ by MnO₄⁻ as the E° MnO₄⁻/Mn²⁺ > E° Cl₂/Cl⁻

MnO₄⁻(aq) + 8H⁺(aq) + 5e⁻ → Mn²⁺ (aq) + 4H₂O(l) Eₐ +1.51V

This would lead to a greater volume of manganate being used and poisonous Cl₂ being produced.

It cannot be nitric acid as it is an oxidising agent. It oxidises Fe²⁺ to Fe³⁺ as E° NO₃⁻/HNO₂ > E° Fe³⁺/Fe²⁺

NO₃⁻ (aq) + 3H⁺(aq) + 2e⁻ → HNO₂(aq) + H₂O(l) Eₐ +0.94V

Fe³⁺ (aq)+e⁻ → Fe²⁺ (aq) Eₐ +0.77 V

This would lead to a smaller volume of manganate being used.
Manganese titration example

A 2.41g nail made from an alloy containing iron is dissolved in 100cm³ acid. The solution formed contains Fe(II) ions. 10cm³ portions of this solution are titrated with potassium manganate (VII) solution of 0.02M. 9.80cm³ of KMnO₄ were needed to react with the solution containing the iron.

What is the percentage of Iron by mass in the nail?

MnO₄⁻(aq) + 8H⁺(aq) + 5Fe²⁺ → Mn²⁺(aq) + 4H₂O + 5Fe³⁺

Step 1 : find moles of KMnO₄
moles = conc x vol
0.02 x 9.8/1000
= 1.96x10⁻⁴ mol

Step 2 : using balanced equation find moles Fe²⁺ in 10cm³
= moles of KMnO₄ x 5
= 9.8x10⁻⁴ mol

Step 3 : find moles Fe²⁺ in 100cm³
= 9.8x10⁻⁴ mol x 10
= 9.8x10⁻³ mol

Step 4 : find mass of Fe in 9.8x10⁻³ mol
mass = moles x MR = 9.8x10⁻³ x 55.8 = 0.547g

Step 5 : find % mass
%mass = 0.547/2.41 x100
= 22.6%

Other useful manganate titrations

With hydrogen peroxide

Ox H₂O₂ → O₂ + 2H⁺ + 2e⁻
Red MnO₄⁻(aq) + 8H⁺(aq) + 5e⁻ → Mn²⁺(aq) + 4H₂O
Overall 2MnO₄⁻(aq) + 6H⁺(aq) + 5H₂O₂ → 5O₂ + 2Mn²⁺(aq) + 8H₂O

With ethanedioate

Ox C₂O₄²⁻ → 2CO₂ + 2e⁻
Red MnO₄⁻(aq) + 8H⁺(aq) + 5e⁻ → Mn²⁺(aq) + 4H₂O
Overall 2MnO₄⁻(aq) + 16H⁺(aq) + 5C₂O₄²⁻(aq) → 10CO₂(g) + 2Mn²⁺(aq) + 8H₂O(l)

With iron (II) ethanedioate both the Fe²⁺ and the C₂O₄²⁻ react with the MnO₄⁻:
1MnO₄⁻ reacts with 5Fe²⁺ and 2 MnO₄⁻ react with 5C₂O₄²⁻:

MnO₄⁻(aq) + 8H⁺(aq) + 5Fe²⁺ → Mn²⁺(aq) + 4H₂O + 5Fe³⁺
2MnO₄⁻(aq) + 16H⁺(aq) + 5C₂O₄²⁻ → 10CO₂(g) + 2Mn²⁺(aq) + 8H₂O
So overall
3MnO₄⁻(aq) + 24H⁺(aq) + 5FeC₂O₄ → 10CO₂ + 3Mn²⁺(aq) + 5Fe³⁺ + 12H₂O

So overall the ratio is 3 MnO₄⁻ to 5 FeC₂O₄

A 1.412 g sample of impure FeC₂O₄·2H₂O was dissolved in an excess of dilute sulfuric acid and made up to 250 cm³ of solution. 25.0 cm³ of this solution decolourised 23.45 cm³ of a 0.0189 mol dm⁻³ solution of potassium manganate (VII).

What is the percentage by mass of FeC₂O₄·2H₂O in the original sample?

Step 1 : find moles of KMnO₄
moles = conc x vol
0.0189 x 23.45/1000
= 4.43x10⁻⁴ mol

Step 2 : using balanced equation find moles FeC₂O₄·2H₂O in 25cm³
= moles of KMnO₄ x 5/3 (see above for ratio)
= 7.39x10⁻⁴ mol

Step 3 : find moles FeC₂O₄·2H₂O in 250 cm³
= 7.39x10⁻⁴ mol x 10
= 7.39x10⁻³ mol

Step 4 : find mass of FeC₂O₄·2H₂O in 7.39x10⁻³ mol
mass= moles x Mr = 7.39x10⁻³ x 179.8 = 1.33g

Step 5 : find % mass
%mass = 1.33/1.412 x100
= 94.1%
**Catalysis**

Catalysts increase reaction rates without getting used up. They do this by **providing an alternative route** with a **lower activation energy**.

<table>
<thead>
<tr>
<th>Transition metals and their compounds can act as heterogeneous and homogeneous catalysts.</th>
<th>A heterogeneous catalyst is in a different phase from the reactants. A homogeneous catalyst is in the same phase as the reactants.</th>
</tr>
</thead>
</table>

**Heterogeneous catalysis**

Heterogeneous catalysts are usually solids whereas the reactants are gaseous or in solution. The reaction occurs at the surface of the catalyst.

**Adsorption of reactants at active sites on the surface may lead to catalytic action.** The active site is the place where the reactants adsorb on to the surface of the catalyst. This can result in the bonds within the reactant molecules becoming weaker, or the molecules being held in a more reactive configuration. There will also be a higher concentration of reactants at the solid surface so leading to a higher collision frequency.

Transition Metals can use the 3d and 4s e- of atoms on the metal surface to form weak bonds to the reactants.

**Strength of adsorption**

The strength of adsorption helps to determine the effectiveness of the catalytic activity. Some metals e.g. W have **too strong** adsorption and so the products cannot be released. Some metals e.g. Ag have **too weak** adsorption, and the reactants do not adsorb in high enough concentration. Ni and Pt have about the right strength and are most useful as catalysts.

**Surface area:**

Increasing the surface area of a solid catalyst will improve its effectiveness. A support medium is often used to maximise the surface area and minimise the cost (e.g. Rh on a ceramic support in catalytic converters).

**Examples of heterogeneous catalysts**

- **V_2O_5** is used as a catalyst in the Contact Process. **Overall equation**: \( 2SO_2 + O_2 \rightarrow 2SO_3 \)
  - **step 1**: \( SO_2 + V_2O_5 \rightarrow SO_3 + V_2O_4 \)
  - **step 2**: \( 2V_2O_4 + O_2 \rightarrow 2V_2O_5 \)

- **Cr_2O_3** catalyst is used in the manufacture of methanol from carbon monoxide and hydrogen. \( CO + 2H_2 \rightarrow CH_3OH \)

- **Poisoning Catalysts**
  
  Catalysts can become poisoned by impurities and consequently have reduced efficiency.

- **Poisoning has a cost implication** e.g. poisoning by sulphur in the Haber Process and by lead in catalytic converters in cars means that catalysts lose their efficiency and may need to be replaced.

- Leaded petrol cannot be used in cars fitted with a catalytic converter since lead strongly adsorbs onto the surface of the catalyst.

**Steps in Heterogeneous Catalysis**

1. Reactants form bonds with atoms at **active sites** on the surface of the catalyst (adsorbed onto the surface).
2. As a result bonds in the reactants are weakened and break.
3. New bonds form between the reactants held close together on catalyst surface.
4. This in turn weakens bonds between product and catalyst and product leaves (desorbs).

**Learn the equations** for this mechanism. Note the oxidation number of the vanadium changes and then changes back. It is still classed as a catalyst as it returns to its original form.

**Fe** is used as a catalyst in the Haber Process. \( N_2 + 3H_2 \rightarrow 2NH_3 \)
Homogeneous catalysis

When catalysts and reactants are in the same phase, the reaction proceeds through an intermediate species.

The intermediate will often have a different oxidation state to the original transition metal. At the end of the reaction the original oxidation state will reoccur. This illustrates importance of variable oxidation states of transition metals in catalysis.

Transition metals can act as homogeneous catalysts because they can form various oxidation states. They are able to donate and receive electrons and are able to oxidize and reduce. This is because the ions contain partially filled sub-shells of d electrons that can easily lose or gain electrons.

Examples of homogeneous catalysts

Learn these 2 examples and equations carefully

**Reaction between iodide and persulfate ions**

The reaction between I\(^{-}\) and S\(_2\)O\(_8\)\(^{2-}\) catalysed by Fe\(^{2+}\)

Overall: S\(_2\)O\(_8\)\(^{2-}\) + 2I\(^{-}\) → 2SO\(_4\)\(^{2-}\) + I\(_2\)

The uncatalysed reaction is very slow because the reaction needs a collision between two negative ions. Repulsion between the ions is going to hinder this – meaning high activation energy

- S\(_2\)O\(_8\)\(^{2-}\) + 2e\(^{-}\) → 2SO\(_4\)\(^{2-}\) \[E^o\] +2.01V
- Fe\(^{3+}\) + e\(^{-}\) → Fe\(^{2+}\) \[E^o\] +0.77V
- I\(_2\) + 2e\(^{-}\) → 2I\(^{-}\) \[E^o\] +0.54V

For a substance to act as a homogenous catalyst its electrode potential must lie in between the electrode potentials of the two reactants, so it can first reduce the reactant with the more positive electrode potential and then in the second step oxidize the reactant with the more negative electrode potential.

Both of the individual stages in the catalysed mechanism involve collision between positive and negative ions and will have lower activation energies.

Catalysed alternative route

**Stage 1**

S\(_2\)O\(_8\)\(^{2-}\) + 2Fe\(^{2+}\) → 2SO\(_4\)\(^{2-}\) + 2Fe\(^{3+}\)

**Stage 2**

2I\(^{-}\) + 2Fe\(^{3+}\) → 2Fe\(^{2+}\) + I\(_2\)

Using E values to find a catalyst only shows that catalysis is possible. It does not guarantee that the rate of reaction will be increased.

Fe\(^{3+}\) ions can also act as the catalyst because the two steps in the catalysed mechanism can occur in any order.

**Autocatalytic Reaction between Ethanedioate and Manganese ions**

The autocatalysis by Mn\(^{2+}\) in titrations of C\(_2\)O\(_4\)\(^{2-}\) with MnO\(_4\)\(^{-}\)

Overall: 2 MnO\(_4\)\(^{-}\) + 5 C\(_2\)O\(_4\)\(^{2-}\) + 16 H\(^+\) → 2 Mn\(^{2+}\) + 10 CO\(_2\) + 8 H\(_2\)O

This is an example of autocatalysis where one of the products of the reaction can catalyse the reaction.

Catalysed alternative route

**Step 1**

4Mn\(^{2+}\) + MnO\(_4\)\(^{-}\) + 8 H\(^+\) → 5Mn\(^{3+}\) + 4 H\(_2\)O

**Step 2**

2 Mn\(^{3+}\) + C\(_2\)O\(_4\)\(^{2-}\) → 2 Mn\(^{2+}\) + 2 CO\(_2\)

The initial uncatalysed reaction is slow because the reaction is a collision between two negative ions which repel each other leading to a high activation energy.

The Mn\(^{2+}\) ions produced act as an autocatalyst and therefore the reaction starts to speed up because they bring about the alternative reaction route with lower activation energy.

The reaction eventually slows as the MnO\(_4\)\(^{-}\) concentration drops.

Following the reaction rate

This can be done by removing samples at set times and titrating to work out the concentration of MnO\(_4\)\(^{-}\).

It could also be done by use of a spectrometer measuring the intensity of the purple colour. This method has the advantage that it does not disrupt the reaction mixture, using up the reactants and it leads to a much quicker determination of concentration.
Constructing a catalysed mechanism for a reaction

Example

The following reaction is catalysed by $\text{Co}^{2+}$ ions in an acidic solution. $\text{SO}_3^{2-} + \frac{1}{2} \text{O}_2 \rightarrow \text{SO}_4^{2-}$.

Write a mechanism for the catalysed reaction by writing two equations involving $\text{Co}^{2+}$ and $\text{Co}^{3+}$ ions.

Split the full equation into its two half equations:

$$\text{SO}_3^{2-} + \frac{1}{2} \text{O}_2 \rightarrow \text{SO}_4^{2-}$$

$$\frac{1}{2} \text{O}_2 + 2\text{H}^+ + 2\text{e}^- \rightarrow \text{H}_2\text{O}$$

$$\text{SO}_3^{2-} + \text{H}_2\text{O} \rightarrow \text{SO}_4^{2-} + 2\text{H}^+ + 2\text{e}^-$$

Add in cobalt to make two new redox equations. Making sure the oxidised cobalt equation is combined with the original reduced half equation and vice versa:

$$\text{Co}^{2+} \rightarrow \text{Co}^{3+} + \text{e}^-$$

$$\frac{1}{2} \text{O}_2 + 2\text{H}^+ + 2\text{Co}^{2+} \rightarrow \text{H}_2\text{O} + 2\text{Co}^{3+}$$

$$\text{Co}^{3+} + \text{e}^- \rightarrow \text{Co}^{2+}$$

$$2\text{Co}^{3+} + \text{SO}_3^{2-} + \text{H}_2\text{O} \rightarrow \text{SO}_4^{2-} + 2\text{H}^+ + 2\text{Co}^{2+}$$

Check your two mechanism equations add up to the original full non-catalysed equation.
Silver Chemistry

Ag⁺ commonly forms linear complexes e.g. [Ag(H₂O)₂]⁺, [Ag(NH₃)₂]⁺, [Ag(S₂O₃)₂]⁻ and [Ag(CN)₂]⁻. All are colourless solutions.

Silver behaves like the transition metals in that it can form complexes and can show catalytic behaviour (although it adsorbs too weakly for many examples).

Silver is unlike the transition metals in that it does not form coloured compounds and does not have variable oxidation states.

Silver complexes all have a +1 oxidation state with a full 4d subshell (4d¹⁰). As it is 4d¹⁰ in both its atom and ion, it does not have a partially filled d subshell and so is not a transition metal by definition. It is not therefore able to do electron transitions between d orbitals that enable coloured compounds to occur.

Reactions of halides with silver nitrate

Fluorides produce no precipitate

Chlorides produce a white precipitate

Ag⁺(aq) + Cl⁻(aq) → AgCl(s)

Bromides produce a cream precipitate

Ag⁺(aq) + Br⁻(aq) → AgBr(s)

Iodides produce a pale yellow precipitate

Ag⁺(aq) + I⁻(aq) → AgI(s)

The silver halide precipitates can be treated with ammonia solution to help differentiate between them if the colours look similar:

Silver chloride dissolves in dilute ammonia to form a complex ion.

AgCl(s) + 2NH₃(aq) → [Ag(NH₃)₂]⁺ (aq) + Cl⁻(aq)

Colourless solution

Silver bromide dissolves in concentrated ammonia to form a complex ion.

AgBr(s) + 2NH₃(aq) → [Ag(NH₃)₂]⁺ (aq) + Br⁻(aq)

Colourless solution

Silver iodide does not react with ammonia – it is too insoluble.

[Ag(NH₃)₂]⁺ is used in Tollen’s reagent to distinguish between aldehydes and ketones. Aldehydes reduce the silver in the Tollen’s reagent to silver.

Red ½ eq: [Ag(NH₃)₂]⁺ + e⁻ → Ag + 2NH₃

Ox ½ eq: CH₃CHO + H₂O → CH₃CO₂H + 2H⁺ + 2e⁻

Using Silver nitrate to work out formulae of chloride containing complexes

Sometimes a compound containing a complex may have Cl⁻ ions acting as ligands inside the complex and Cl⁻ ions outside the complex attracted ionically to it. If silver nitrate is added to such a compound it will only form the silver chloride precipitate with the free chloride ions outside of the complex.

e.g. Co(NH₃)₆Cl₃ reacts on a 1:3 mole ratio with silver nitrate as there are three free Cl⁻ ions. So all 3 Cl⁻ ions are outside the complex.

[e.g. Cr(NH₃)₄Cl₃ reacts on a 1:2 mole ratio with silver nitrate as there are two free Cl⁻ ions. So 1 Cl⁻ is a ligand and 2 are outside the complex.

[e.g. Cr(NH₃)₄Cl₃ reacts on a 1:1 mole ratio with silver nitrate as there is one free Cl⁻ ion. So 2 Cl⁻ ions are ligands and 1 is outside the complex.
